Codebook

BASIN: the ocean where the storm is located (e.g. AL for Atlantic or EP for East Pacific).

Coordinates: a set of two numbers representing the latitude and longitude for a certain point on Earth.

DTG: the valid date and time of the data in UTC format.

Feature: the combination of a geometry and its associated attributes that make up the contents of a geospatial data file.

Geometry: a geometric shape represented with geospatial coordinates. Types of geometries include points, lines, and polygons.

INTENSITY: the highest 1-minute average wind speed in knots at the center of the storm at particular point in time.

LAT: the latitude, the distance north or south of the equator, of the center of the storm.

LON: the longitude, the distance east or west of the prime meridian, of the center of the storm.

MSLP: the mean sea level pressure at the storm's center in millibars.

RADII: the wind speed in knots associated with a radii feature.

STORMNAME: the name given to the storm by the National Hurricane Center (e.g. Matthew)

STORMNUM: the sequential number given to the storm based on the season and the basin it started in. If a storm is the first storm in the Atlantic to be tracked by the National Hurricane Center in a certain year, its STORMNUM would be 1.

STORMTYPE: the category of the storm based on its intensity (e.g. TD for Tropical Depression, TS for Tropical Storm, HU for Hurricane, and DB for Disturbance).

SS: the Saffir Simpson Hurricane Scale. This is the scale used in the U.S. to rate hurricanes based on their intensity. The scale goes from 1-5, with 5 being the most intense hurricane.

TAU: The number of hours from the forecast valid time for which a forecast is made. Normally this value is 0 because the forecast is normally made at the same time it becomes valid.
